Abstract of the Disclosure

The present invention relates to an amplifying circuit that can change load drivability responding to load conditions, and reduce power consumption. The amplifying circuit according to the present invention comprises an amplifying means that amplifies input signals a first time to generate a first and a second amplified signals through a first and a transistors, and further amplifies the first and amplified signals once again through a third and a fourth for final outputs; a detecting means transistors, detecting the first and second amplified signals from the amplifying means and generating a first and a second detection and а load drivability control means controlled by the first and second detection signals from the detecting means to change load drivability of the amplifying means.
